# MAPPINGS OF FINITE DISTORTION ON METRIC SURFACES 

DAMARIS MEIER AND KAI RAJALA

#### Abstract

We investigate basic properties of mappings of finite distortion $f: X \rightarrow \mathbb{R}^{2}$, where $X$ is any metric surface, i.e., metric space homeomorphic to a planar domain with locally finite 2-dimensional Hausdorff measure. We introduce lower gradients, which complement the upper gradients of Heinonen and Koskela, to study the distortion of non-homeomorphic maps on metric spaces.

We extend the Iwaniec-Šverák theorem to metric surfaces: a nonconstant $f: X \rightarrow \mathbb{R}^{2}$ with locally integrable distortion is continuous, open and discrete. We also extend the Hencl-Koskela theorem by showing that if $f$ is moreover injective then $f^{-1}$ is a Sobolev map.

## 1. Introduction

1.1. Background. Let $\Omega \subset \mathbb{R}^{2}$ be a domain. We say that map $f: \Omega \rightarrow \mathbb{R}^{2}$ in the Sobolev space $W_{\text {loc }}^{1,2}\left(\Omega, \mathbb{R}^{2}\right)$ has finite distortion if there is a measurable function $K: \Omega \rightarrow[1, \infty)$ so that

$$
\begin{equation*}
\|D f(x)\|^{2} \leq K(x) J_{f}(x) \quad \text { for a.e. } x \in \Omega \text {. } \tag{1.1}
\end{equation*}
$$

Here $\|D f(x)\|$ and $J_{f}(x)$ are the operator norm and determinant of $D f(x)$, respectively.

If $K(x)=1$ for almost every $x \in \Omega$, then (1.1) is valid if and only if $f$ is complex analytic. The basic topological properties of non-constant analytic functions are continuity, openness and discreteness (the preimage of every point is discrete in $\Omega$ ).

By Stoilow factorization (see AIM09, Chapter 5.5], LP20) non-constant quasiregular maps, i.e., maps $f$ satisfying (1.1) with constant function $K(x)=$ $K \geq 1$, admit a factorization $f=g \circ h$, where $h$ is a quasiconformal homeomorphism and $g$ is analytic. In particular, every such $f$ is also continuous, open and discrete.

In IŠ93 Iwaniec and Šverák showed that boundedness of $K(x)$ may be replaced with local integrability.
Theorem 1.1 (Iwaniec-Šverák theorem). Suppose $f \in W_{l o c}^{1,2}\left(\Omega, \mathbb{R}^{2}\right)$ is nonconstant and satisfies (1.1) for some locally integrable $K(x)$. Then $f$ is continuous, open and discrete.

[^0]The assumption on $K(x)$ is essentially best possible (see Bal81] and (HR13). Since the work of Iwaniec and Šverák [IS93], a rich theory of mappings of finite distortion has been developed (see [AIM09], HK14), with applications to PDE, complex dynamics, inverse problems and non-linear elasticity theory, among other fields.

The theory extends to $W_{\text {loc }}^{1,1}$-maps with exponentially integrable distortion and also to higher dimensions, where continuity, openness and discreteness of quasiregular maps was proved by Reshetnyak already in the 1960s (see (Reš67]). Reshetnyak's theorem has been extended to spatial mappings of finite distortion by several authors (see [VjGd76], VM98], KKM01], IKO01, [IM01, $\mathrm{KKM}^{+}$03], OZ08, (Raj10], HR13).

Partially motivated by works of Heinonen-Rickman HR02], HeinonenSullivan HS02 and Heinonen-Keith HK11 on BLD- and bi-Lipschitz parametrizations of metric spaces, Kirsilä [Kir16] furthermore extended Reshetnyak's theorem to maps $f: X \rightarrow \mathbb{R}^{n}$, where $X$ is a generalized $n$-manifold satisfying assumptions such as Ahlfors $n$-regularity and Poincaré inequality.

In this paper we extend the Iwaniec-Šverák theorem to maps $f: X \rightarrow \mathbb{R}^{2}$, where $X$ is a metric surface, i.e., a metric space homeomorphic to a domain in $\mathbb{R}^{2}$ with locally finite 2 -dimensional Hausdorff measure. The novelty of our results is that we do not impose any additional conditions on $X$.

Our research is partially inspired by recent advances on the uniformization problem on metric surfaces (see [BK02], Raj17], [Iko22, [MW21], Mei23], [NR23], NR22]) and the properties of the associated homeomorphisms, such as quasiconformal maps $f: X \rightarrow \mathbb{R}^{2}$. It is desirable to explore the properties of non-homeomorphic maps on metric surfaces. The aim of our paper is to provide the first results in this direction.
1.2. Mappings of finite distortion on metric surfaces. A (euclidean) metric surface $X$ is a metric space homeomorphic to a domain $U \subset \mathbb{R}^{2}$ and with locally finite 2 -dimensional Hausdorff measure. Below, $\mathcal{H}^{2}$ will always be the reference measure on $X$.

Let $X$ and $Y$ be metric surfaces. We want to establish what it means for a map $f: X \rightarrow Y$ to have finite distortion. We first observe that in the euclidean case every mapping of finite distortion is sense-preserving. This follows from inequality (1.1) by applying non-negativity of the Jacobian determinant and integration by parts, a method which is not available in our generality. We call $f: X \rightarrow Y$ sense-preserving if for any domain $\Omega$ compactly contained in $X$ so that $\left.f\right|_{\partial \Omega}$ is continuous it follows that $\operatorname{deg}(y, f, \Omega) \geq 1$ for any $y \in f(\Omega) \backslash f(\partial \Omega)$. Here deg is the local topological degree of $f$ (see [Ric93, I.4]).

We apply the theory of Sobolev spaces based on upper gradients ([HKST15)). A Borel function $\rho^{u}: X \rightarrow[0, \infty]$ is an upper gradient of $f: X \rightarrow \bar{Y}$, if

$$
\begin{equation*}
d_{Y}(f(x), f(y)) \leq \int_{\gamma} \rho^{u} d s \tag{1.2}
\end{equation*}
$$

for all $x, y \in X$ and every rectifiable curve $\gamma$ in $X$ joining $x$ and $y$. We say that $f$ belongs to the Sobolev space $N_{\text {loc }}^{1,2}(X, Y)$ if $f$ has an upper gradient $\rho^{u} \in L_{\text {loc }}^{2}(X)$ and if $d_{Y}(y, f(\cdot)) \in L_{\text {loc }}^{2}(X)$ for some $y \in Y$ (see Section 2.3).

It follows from the proof of [EIR22, Theorem 1.4] that a sense-preserving map $f \in N_{\text {loc }}^{1,2}\left(X, \mathbb{R}^{2}\right)$ is continuous (see Remark 2.3). Such an $f$ also satisfies Lusin's Condition ( $N$ ): if $E \subset X$ and $\mathcal{H}^{2}(E)=0$, then $|f(E)|_{2}=0$ (see Remark 2.8). The converse implication does not hold ( Raj17, Section 17]).

In order to define the distortion of $f$, we introduce lower gradients: a Borel function $\rho^{l}: X \rightarrow[0, \infty]$ is a lower gradient of $f: X \rightarrow Y$, if

$$
\begin{equation*}
\ell(f \circ \gamma) \geq \int_{\gamma} \rho^{l} d s \quad \text { for every rectifiable curve } \gamma \text { in } X \text {. } \tag{1.3}
\end{equation*}
$$

Our definition is motivated by the observation that upper gradient inequality (1.2) is equivalent to the reverse inequality of (1.3) for $\rho^{u}$ (see Section 2.3). Every $f \in N_{\mathrm{loc}}^{1,2}(X, Y)$ has an essentially unique minimal weak upper gradient $\rho_{f}^{u}$ (see Section 2.3. Similarly, we prove in Section 7 that every such $f$ has an essentially unique maximal weak lower gradient $\rho_{f}$.

We say that a sense-preserving $f \in N_{\text {loc }}^{1,2}(X, Y)$ has finite distortion if there is a measurable $K: X \rightarrow[1, \infty)$ such that

$$
\begin{equation*}
\rho_{f}^{u}(x) \leq K(x) \cdot \rho_{f}^{l}(x) \quad \text { for almost every } x \in X \tag{1.4}
\end{equation*}
$$

The distortion $K_{f}$ of $f$ is

$$
K_{f}(x):= \begin{cases}\frac{\rho_{f}^{u}(x)}{\rho_{f}^{l}(x)}, & \text { if } \rho_{f}^{l}(x) \neq 0 \\ 1, & \text { if } \rho_{f}^{l}(x)=0\end{cases}
$$

Our main result is the following extension of the Iwaniec-Šverák theorem. Here $X$ is any metric surface.
Theorem 1.2. Let $f \in N_{l o c}^{1,2}\left(X, \mathbb{R}^{2}\right)$ be a non-constant mapping of finite distortion with $K_{f} \in L_{l o c}^{1}(X)$. Then $f$ is open and discrete.

Generalizing the euclidean result by Hencl-Koskela (who assumed $W^{1,1_{-}}$ regularity, see [HK06]), we show that if $f$ is furthermore a homeomorphism, then the inverse is also a Sobolev map.
Theorem 1.3. Let $f \in N_{l o c}^{1,2}\left(X, \mathbb{R}^{2}\right)$ be an injective mapping of finite distortion with $K_{f} \in L_{l o c}^{1}(X)$. Then $f^{-1} \in N_{l o c}^{1,2}(f(X), X)$.

Examples in Bal81 ( $f_{0}$ in Proposition 6.1 below, see also (HR13) and HK06, Example 1.4], respectively, show that condition $K_{f} \in L_{\mathrm{loc}}^{1}(X)$ is sharp both in Theorem 1.2 and in Theorem 1.3, even if $X=\mathbb{R}^{2}$.

We show in Section 6 that there are metric surfaces $X$ which do not admit any quasiconformal maps $h: X \rightarrow \mathbb{R}^{2}$ but do admit maps $f: X \rightarrow \mathbb{R}^{2}$ satisfying the assumptions of Theorem 1.2. We do not know if such surfaces exist if we require $K_{f}$ to be bounded instead of $L_{\text {loc }}^{1}$ (see Question 6.2).

Previous approaches to analytic distortion of maps between metric spaces are mostly based on distortion inequality

$$
\begin{equation*}
\left(\rho_{f}^{u}\right)^{2} \leq K J_{f} \quad \text { a.e. }, \tag{1.5}
\end{equation*}
$$

where $J_{f}$ is the area derivative of $f$. Inequality (1.5) is equivalent to (1.4) in the euclidean setting, and also provides a rich theory for homeomorphisms between metric spaces. However, in our generality of metric surfaces, (1.5) is not strong enough for non-homeomorphic maps. We therefore develop our results based on the lower gradient approach which is strong enough to overcome the lack of differentiability. We discuss the different approaches in Section 6 .

The definition of a metric surface can be relaxed by requiring $X$ to be homeomorphic to an oriented topological surface $M$ instead of a domain in $\mathbb{R}^{2}$. Our definitions and results are local and remain valid under the relaxed definition. We state them only for euclidean metric surfaces to simplify the presentation.

This paper is organized as follows. In Section 2 we recall the background on Analysis in metric spaces needed to prove our main results. In Section 3 we prove an area inequality for maps on the rectifiable part of a metric surface which involves lower gradients and may be of independent interest. We prove Theorems 1.2 and 1.3 in Sections 4 and 5 , respectively.

The proofs are based on three main tools: the coarea inequality for Sobolev functions on metric surfaces by Meier-Ntalampekos MN23 and Esmayli-Ikonen-Rajala (EIR22], weakly quasiconformal parametrizations of metric surfaces by Ntalampekos-Romney [NR22, [NR23] and Meier-Wenger [MW21], and the area inequality proved in Section 3. In addition, to prove Theorem 1.2 we apply estimates inspired by the value distribution theory of quasiregular mappings (see Ric93).

In Section 6, we discuss connections between our results and the uniformization problem on metric surfaces, as well as different definitions of mappings with controlled distortion. Finally, in Section 7 we prove the existence of maximal weak lower gradients.

## 2. Preliminaries

2.1. Basic definitions and notations. Let $(X, d)$ be a metric space. We denote the open and closed ball in $X$ of radius $r>0$ centered at a point $x \in X$ by $B(x, r)$ and $\bar{B}(x, r)$, respectively. When $X=\mathbb{R}^{2}$ we use notation $\mathbb{D}(x, r)$ instead of $B(x, r)$.

A set $\Omega \subset X$ homeomorphic to the unit disc $\mathbb{D}(0,1)$ is a Jordan domain in $X$ if its boundary $\partial \Omega \subset X$ is a Jordan curve in $X$, i.e., a subset of $X$ homeomorphic to $\mathbb{S}^{1}$. The image of a curve $\gamma$ in $X$ is indicated by $|\gamma|$ and the length by $\ell(\gamma)$.

A curve $\gamma$ is rectifiable if $\ell(\gamma)<\infty$ and locally rectifiable if each of its compact subcurves is rectifiable. Moreover, a curve $\gamma:[a, b] \rightarrow X$ is geodesic if $\ell(\gamma)=d(\gamma(a), \gamma(b))$. A curve $\gamma:[0, \ell(\gamma)] \rightarrow X$ is parametrized by arclength
if $\ell\left(\left.\gamma\right|_{I}\right)=|I|_{1}$ for every interval $I \subset[0, \ell(\gamma)]$. Here, $|\cdot|_{n}$ denotes the $n$ dimensional Lebesgue measure.

For $s \geq 0$, we denote the $s$-dimensional Hausdorff measure of $A \subset X$ by $\mathcal{H}^{s}(A)$. The normalizing constant is chosen so that $|V|_{n}=\mathcal{H}^{n}(V)$ for open subsets $V$ of $\mathbb{R}^{n}$.

We equip $X$ with $\mathcal{H}^{2}$. Let $L^{p}(X)\left(L_{\mathrm{loc}}^{p}(X)\right)$ denote the space of $p$ integrable (locally $p$-integrable) Borel functions from $X$ to $\mathbb{R} \cup\{-\infty, \infty\}$. Here locally $p$-integrable means $p$-integrable on compact subsets. We say that a subdomain $G$ of $X$ is compactly contained in $X$ if the closure $\bar{G}$ is compact.
2.2. Modulus. Let $X$ be a metric space and $\Gamma$ be a family of curves in $X$. A Borel function $g: X \rightarrow[0, \infty]$ is admissible for $\Gamma$ if $\int_{\gamma} g d s \geq 1$ for all locally rectifiable curves $\gamma \in \Gamma$. We define the (2-)modulus of $\Gamma$ as

$$
\operatorname{Mod} \Gamma=\inf _{g} \int_{X} g^{2} d \mathcal{H}^{2}
$$

where the infimum is taken over all admissible functions $g$ for $\Gamma$. If there are no admissible functions for $\Gamma$ we set $\operatorname{Mod} \Gamma=\infty$. A property is said to hold for almost every curve in $\Gamma$ if it holds for every curve in $\Gamma \backslash \Gamma_{0}$ for some family $\Gamma_{0} \subset \Gamma$ with $\operatorname{Mod}\left(\Gamma_{0}\right)=0$. In the definition of $\operatorname{Mod}(\Gamma)$, the infimum can equivalently be taken over all weakly admissible functions, i.e., Borel functions $g: X \rightarrow[0, \infty]$ such that $\int_{\gamma} g \geq 1$ for almost every locally rectifiable curve $\gamma \in \Gamma$.
2.3. Metric Sobolev spaces. Let $f: X \rightarrow Y$ be a map between metric spaces. A Borel function $\rho^{u}: X \rightarrow[0, \infty]$ is an upper gradient of $f$ if

$$
\begin{equation*}
d_{Y}(f(x), f(y)) \leq \int_{\gamma} \rho^{u} d s \tag{2.1}
\end{equation*}
$$

for all $x, y \in X$ and every rectifiable curve $\gamma$ in $X$ joining $x$ and $y$. If the upper gradient inequality (2.1) holds for almost every rectifiable curve $\gamma$ in $X$ joining $x$ and $y$ we call $\rho^{u}$ weak upper gradient of $f$.

The Sobolev space $N^{1,2}(X, Y)$ is the space of Borel maps $f: X \rightarrow Y$ with upper gradient $\rho^{u} \in L^{2}(X)$ such that $x \mapsto d_{Y}(y, f(x))$ is in $L^{2}(X)$ for some and thus any $y \in Y$. The space $N_{\mathrm{loc}}^{1,2}(X, Y)$ is defined in the obvious manner.

Each $f \in N_{\text {loc }}^{1,2}(X, Y)$ has a minimal weak upper gradient $\rho_{f}^{u}$, i.e., for any other weak upper gradient $\rho^{u}$ we have $\rho_{f}^{u} \leq \rho^{u}$ almost everywhere. Moreover, $\rho_{f}^{u}$ is unique up to a set of measure zero. See monograph HKST15 for more background on metric Sobolev spaces.

We apply a notion of "minimal stretching" which compliments the "maximal stretching" represented by upper gradients. To motivate the definition, notice that the upper gradient inequality $\sqrt{2.1}$ ) is equivalent to

$$
\ell(f \circ \gamma) \leq \int_{\gamma} \rho^{u} d s \quad \text { for every rectifiable curve } \gamma \text { in } X
$$

We call a Borel function $\rho^{l}: X \rightarrow[0, \infty]$ a lower gradient of $f$ if

$$
\begin{equation*}
\ell(f \circ \gamma) \geq \int_{\gamma} \rho^{l} d s \quad \text { for every rectifiable curve } \gamma \text { in } X . \tag{2.2}
\end{equation*}
$$

If the lower gradient inequality $(2.2)$ holds for almost every rectifiable $\gamma$, we call $\rho^{l}$ weak lower gradient of $f$. Note that 0 is always a lower gradient.

Each $f \in N_{\text {loc }}^{1,2}(X, Y)$ has a maximal weak lower gradient $\rho_{f}^{l}$, i.e., for any other weak lower gradient $\rho^{l}$ we have $\rho_{f}^{l} \geq \rho^{l}$ almost everywhere. Moreover, $\rho_{f}^{l}$ is unique up to a set of measure zero. The proof is analogous to the existence of minimal weak upper gradients, see [HKST15, Theorem 6.3.20]. For completeness, we provide a proof in Section 7.
2.4. Coarea inequality on metric surfaces. We state the following coarea inequality for Lipschitz functions, which is a consequence of EHa21, Theorem 1.1] (see [EIR22, Section 5]). Here, $\operatorname{Lip}(u)$ denotes the pointwise Lipschitz constant of a Lipschitz function $u: X \rightarrow \mathbb{R}$, defined by

$$
\operatorname{Lip}(u)(x)=\limsup _{x \neq y \rightarrow x} \frac{|u(y)-u(x)|}{d(x, y)}
$$

Theorem 2.1 (Lipschitz coarea inequality). Let $X$ be a metric space and $u: X \rightarrow \mathbb{R}$ a Lipschitz function. Then

$$
\int_{\mathbb{R}}^{*} \int_{u^{-1}(t)} g d \mathcal{H}^{1} d t \leq \frac{4}{\pi} \int_{X} g \cdot \operatorname{Lip}(u) d \mathcal{H}^{2}
$$

for every Borel measurable $g: X \rightarrow[0, \infty]$.
Here $\int^{*}$ denotes the upper integral, which is equal to Lebesgue integral for measurable functions. An important tool throughout this work will be the following coarea inequality for continuous Sobolev functions on metric surfaces.

Theorem 2.2 (Sobolev coarea inequality, MN23, Theorem 1.6]). Let $X$ be a metric surface and $v: X \rightarrow \mathbb{R}$ be a continuous function in $N_{l o c}^{1,2}(X)$.
(1) If $\mathcal{A}_{v}$ denotes the union of all non-degenerate components of the level sets $v^{-1}(t), t \in \mathbb{R}$, of $v$, then $\mathcal{A}_{v}$ is a Borel set.
(2) For every Borel function $g: X \rightarrow[0, \infty]$ we have

$$
\int^{*} \int_{v^{-1}(t) \cap \mathcal{A}_{v}} g d \mathcal{H}^{1} d t \leq \frac{4}{\pi} \int g \cdot \rho_{v}^{u} d \mathcal{H}^{2}
$$

Theorem 2.2 generalizes the coarea inequality for monotone Sobolev functions established in EIR22. Here $v: X \rightarrow \mathbb{R}$ is called a weakly monotone function if for every open $\Omega$ compactly contained in $X$

$$
\sup _{\Omega} v \leq \sup _{\partial \Omega} v<\infty \quad \text { and } \quad \inf _{\Omega} v \geq \inf _{\partial \Omega} v>-\infty
$$

A continuous weakly monotone function is monotone.
Remark 2.3. In the proof of [EIR22, Theorem 1.4] the coarea inequality for monotone Sobolev functions is used to show that every weakly monotone function $v \in N_{\text {loc }}^{1,2}(X, \mathbb{R})$ is continuous and hence monotone. Continuity of a sense-preserving map $f \in N_{\text {loc }}^{1,2}\left(X, \mathbb{R}^{2}\right)$ now follows by applying the exact same proof strategy while replacing weak monotonicity with sensepreservation and the coarea inequality for monotone Sobolev maps with Theorem 2.2.
2.5. Metric differentiability. Let $(Y, d)$ be a complete metric space and $U \subset \mathbb{R}^{n}, n \geq 1$, a domain. We say that $h: U \rightarrow Y$ is approximately metrically differentiable at $z \in U$ if there exists a seminorm $N_{z}$ on $\mathbb{R}^{2}$ for which

$$
\text { ap } \lim _{y \rightarrow z} \frac{d(h(y), h(z))-N_{z}(y-z)}{y-z}=0 .
$$

Here, ap lim denotes the approximate limit (see EG92, Section 1.7.2]). If such a seminorm exists, it is unique and is called approximate metric derivative of $h$ at $z$, denoted ap $\operatorname{md} h_{z}$. The following result follows from LW18, Lemma 3.1].
Lemma 2.4. Let $X$ and $Y$ be metric surfaces and $f \in N_{l o c}^{1,2}(X, Y)$. Almost every curve $\gamma:[a, b] \rightarrow X$ parametrized by arclength satisfies

$$
\int_{f \circ \gamma} g d s=\int_{a}^{b} g(f(\gamma(t))) \cdot \operatorname{ap} \operatorname{md}(f \circ \gamma)_{t} d t
$$

for all Borel measurable $g: Y \rightarrow[0, \infty]$.
Lemma 2.4 leads to the following properties of upper and lower gradients (see HKST15, Proposition 6.3.3] for a proof involving upper gradients).

Corollary 2.5. Let $X$ and $Y$ be metric surfaces and $f \in N_{l o c}^{1,2}(X, Y)$. Almost every curve $\gamma:[a, b] \rightarrow X$ parametrized by arclength satisfies the following properties.
(1) $f$ is absolutely continuous on $\gamma$,
(2) $\rho_{f}^{l}(\gamma(t)) \leq \operatorname{ap} \operatorname{md}(f \circ \gamma)_{t} \leq \rho_{f}^{u}(\gamma(t))$ for almost every $a<t<b$,
(3) if $g: Y \rightarrow[0, \infty]$ is Borel measurable, then

$$
\int_{\gamma} \rho_{f}^{l} \cdot(g \circ f) d s \leq \int_{f \circ \gamma} g d s \leq \int_{\gamma} \rho_{f}^{u} \cdot(g \circ f) d s
$$

2.6. Area formula on euclidean domains. Suppose $U \subset \mathbb{R}^{2}$ is a domain and $h \in N_{\mathrm{loc}}^{1,2}(U, Y)$. Then $U$ can be covered up to a set of measure zero by countably many disjoint measurable sets $G_{j}, j \in \mathbb{N}$, such that $\left.h\right|_{G_{j}}$ is Lipschitz. In particular, outside a set of measure zero $G_{0} \subset U, h$ satisfies Lusin's condition (N) (see (HKST15, Theorem 8.1.49]).

By LW17, Proposition 4.3], every $h \in N_{\text {loc }}^{1,2}(U, Y)$ is approximately metrically differentiable at a.e. $z \in U$. The following area formula follows from

Kar07, Theorem 3.2]. Here, the Jacobian $J\left(N_{z}\right)$ of a seminorm $N_{z}$ on $\mathbb{R}^{2}$ is zero if $N_{z}$ is not a norm and $J\left(N_{z}\right)=\pi /\left|\left\{y \in \mathbb{R}^{2}: N_{z}(y) \leq 1\right\}\right|_{2}$ otherwise.

Theorem 2.6 (Area formula). If $h \in N_{\text {loc }}^{1,2}(U, Y)$, then there exists $G_{0} \subset U$ with $\mathcal{H}^{2}\left(G_{0}\right)=0$ such that for every measurable set $A \subset U \backslash G_{0}$ we have

$$
\begin{equation*}
\int_{A} J\left(\operatorname{ap} \operatorname{md} h_{z}\right) d \mathcal{H}^{2}=\int_{Y} N(y, h, A) d \mathcal{H}^{2} \tag{2.3}
\end{equation*}
$$

Here, $N(y, h, A)$ denotes the multiplicity of $y \in Y$ with respect to $h$ in $A$ :

$$
\begin{equation*}
N(y, h, A):=\#\{z \in A: h(z)=y\} \tag{2.4}
\end{equation*}
$$

2.7. Weakly quasiconformal parametrizations. A map $h: X \rightarrow Y$ between metric surfaces is cell-like if the preimage of each point is a continuum that is contractible in each of its open neighborhoods. A continuous, surjective, proper and cell-like map $h: X \rightarrow Y$ is weakly C-quasiconformal if

$$
\operatorname{Mod} \Gamma \leq C \operatorname{Mod} h(\Gamma)
$$

holds for every family of curves $\Gamma$ in $X$. It follows from Wil12, Theorem 1.1] that every weakly quasiconformal map $h: X \rightarrow Y$ is contained in $N_{\text {loc }}^{1,2}(X, Y)$.

It was shown in [NR22] that any metric surface admits a weakly quasiconformal parametrization, see also [NR23], MW21, [Mei23].

Theorem 2.7 ([NR22, Theorem 1.2]). Let $X$ be any metric surface. There is a weakly $(4 / \pi)$-quasiconformal $u: U \rightarrow X$, where $U \subset \mathbb{R}^{2}$ is a domain.
Remark 2.8. Condition (N) for sense-preserving maps $f \in N_{\mathrm{loc}}^{1,2}\left(X, \mathbb{R}^{2}\right)$ can be proved using the area formula and Theorem 2.7 as follows: suppose $E \subset X$ and $\mathcal{H}^{2}(E)=0$, and let $u: U \rightarrow X$ be a (sense-preserving) weakly $(4 / \pi)$-quasiconformal parametrization of $X$ provided by Theorem 2.7. Define $h: U \rightarrow \mathbb{R}^{2}$ by $h:=f \circ u$. Then $u \in N_{\text {loc }}^{1,2}(U, X)$ and $h \in N_{\text {loc }}^{1,2}\left(U, \mathbb{R}^{2}\right)$.

By Theorem 2.6 there exists $G_{0} \subset U$ with $\left|G_{0}\right|_{2}=0$ and such that (2.3) holds for $u$ and $h$ and every measurable set $A \subset U \backslash G_{0}$. We set $X_{0}:=u\left(G_{0}\right)$. Now $h$ is sense-preserving and thus monotone. Therefore, $h$ satisfies Condition (N) by MM95. In particular, with the above notation,

$$
|f(E)|_{2} \leq \int_{u^{-1}(E)} J\left(\operatorname{ap} \mathrm{md} h_{z}\right) d z
$$

On the other hand, applying Theorem 2.6 to $u$ shows that

$$
\int_{u^{-1}(E)} J\left(\operatorname{ap} \mathrm{md} u_{z}\right) d z \leq \mathcal{H}^{2}(E)=0
$$

and so $J\left(\right.$ ap md $\left.u_{z}\right)=0$ almost everywhere in $u^{-1}(E)$. Since $u$ is weakly quasiconformal, it moreover follows that ap md $u_{z}=0$. Then, by Lemmas 2.9 and 2.10 below, $J\left(\right.$ ap md $\left.h_{z}\right)=0$ almost everywhere in $u^{-1}(E)$ as well. We conclude that $|f(E)|_{2}=0$.
2.8. Distortion of Sobolev maps. Let $U \subset \mathbb{R}^{2}$ be a domain. We define the maximal and minimal stretches of $h \in N_{\text {loc }}^{1,2}(U, Y)$ at points of approximate differentiability by
$L_{h}(z)=\max \left\{\operatorname{ap} \operatorname{md} h_{z}(v):|v|=1\right\}, \quad l_{h}(z)=\min \left\{\operatorname{ap} \operatorname{md} h_{z}(v):|v|=1\right\}$.
Recall that maps $h \in N_{\mathrm{loc}}^{1,2}(U, Y)$ are approximately differentiable almost everywhere.
Lemma 2.9. Let $h \in N_{l o c}^{1,2}(U, Y)$. Then $L_{h}$ and $l_{h}$ are representatives of the minimal weak upper gradient and the maximal weak lower gradient of $h$, respectively. Moreover,

$$
\begin{equation*}
2^{-1} L_{h}(z) l_{h}(z) \leq J\left(\operatorname{ap} \operatorname{md} h_{z}\right) \leq 2 L_{h}(z) l_{h}(z) \tag{2.5}
\end{equation*}
$$

at points of approximate differentiability.
Proof. The first claim concerning upper gradients is MN23, Lemma 2.14]. A slight modification of the proof gives the claim concerning lower gradients.

Towards 2.5), we may assume that ap md $h_{z}$ is a norm. Then the unit ball $B_{z}$ of ap $\mathrm{md} h_{z}(v)$ contains a unique ellipse of maximal area $E_{z}$, called the John ellipse of $B_{z}$, which satisfies

$$
\begin{equation*}
E_{z} \subset B_{z} \subset \sqrt{2} E_{z} \tag{2.6}
\end{equation*}
$$

see Bal97, Theorem 3.1]. Let $N_{z}$ be the norm whose unit ball is $E_{z}$, and

$$
M_{z}=\max \left\{N_{z}(v):|v|=1\right\}, \quad m_{z}=\min \left\{N_{z}(v):|v|=1\right\}
$$

Then $J\left(N_{z}\right)=\pi /\left|E_{z}\right|_{2}=M_{z} m_{z}$, and (2.6) gives

$$
L_{h}(z) l_{h}(z) \leq M_{z} m_{z}=J\left(N_{z}\right)=2 \pi /\left|\sqrt{2} E_{z}\right|_{2} \leq 2 \pi /\left|B_{z}\right|_{2}=2 J\left(\operatorname{ap} \operatorname{md} h_{z}\right)
$$

On the other hand, (2.6) also gives

$$
J\left(\operatorname{ap} \operatorname{md} h_{z}\right) \leq J\left(N_{z}\right)=M_{z} m_{z} \leq 2 L_{h}(z) l_{h}(z)
$$

The proof is complete.
We will apply distortion estimates on composed mappings.
Lemma 2.10. Let $X$ and $Y$ be metric surfaces and $U \subset \mathbb{R}^{2}$ a domain, $u: U \rightarrow X$ weakly quasiconformal, and $f \in N_{l o c}^{1,2}(X, Y)$. Then

$$
l_{f \circ u}(z) \geq \rho_{f}^{l}(u(z)) \cdot l_{u}(z) \quad \text { and } \quad L_{f \circ u}(z) \leq \rho_{f}^{u}(u(z)) \cdot L_{u}(z)
$$

for almost every $z \in U$.
Proof. Let $\Gamma_{0}$ be the family of paths $\gamma$ in $U$ so that $l_{u}$ does not satisfy the lower gradient inequality 2.2 for $u$ on some subcurve of $\gamma$ or $\rho_{f}^{l}$ does not satisfy the lower gradient inequality for $f$ on some subcurve of $u \circ \gamma$. Then, since $u$ is weakly quasiconformal and $l_{u}, \rho_{f}^{l}$ are weak lower gradients (Lemma 2.9), we conclude that $\operatorname{Mod}\left(\Gamma_{0}\right)=0$. Applying Corollary 2.5, we have

$$
\ell(f \circ u \circ \gamma) \geq \int_{u \circ \gamma} \rho_{f}^{l} d s \geq \int_{\gamma}\left(\rho_{f}^{l} \circ u\right) \cdot l_{u} d s
$$

for every $\gamma \notin \Gamma_{0}$ parametrized by arclength. We conclude that $\left(\rho_{f}^{l} \circ u\right) \cdot l_{u}$ is a weak lower gradient of $f \circ u$. But $l_{f \circ u}$ is a maximal weak lower gradient of $f \circ u$ by Lemma 2.9. The first inequality follows. The second inequality is proved in a similar way.

## 3. Area inequality on Metric surfaces

Let $X$ and $Y$ be metric surfaces. In this section we establish Theorem 3.1, an area inequality for Sobolev maps in $N_{\mathrm{loc}}^{1,2}(X, Y)$ on measurable subsets of the rectifiable part of $X$. We apply Theorem 3.1 in Sections 4 and 5 below to prove our main results, Theorems 1.2 and 1.3 .

As in Remark 2.8, let $u: U \rightarrow X$ be a weakly $(4 / \pi)$-quasiconformal parametrization of $X$ provided by Theorem 2.7, and $h: U \rightarrow Y, h:=f \circ u$. Then $u \in N_{\text {loc }}^{1,2}(U, X)$ and $h \in N_{\text {loc }}^{1,2}(U, Y)$. By Theorem 2.6, there exists $G_{0} \subset U$ with $\left|G_{0}\right|_{2}=0$ and such that (2.3) holds for both $u$ and $h$ and every measurable set $A \subset U \backslash G_{0}$. We set $X_{0}:=u\left(G_{0}\right)$.

Theorem 3.1 (Area inequality). If $g: Y \rightarrow[0, \infty]$ and $E \subset X \backslash X_{0}$ are Borel measurable, then

$$
\int_{E} g(f(x)) \cdot \rho_{f}^{u}(x) \rho_{f}^{l}(x) d \mathcal{H}^{2} \leq 4 \sqrt{2} \int_{Y} g(y) \cdot N(y, f, E) d y .
$$

In order to establish Theorem 3.1, we make use of the following proposition which can be seen as a counterpart to Lemma 2.10 .
Proposition 3.2. Let $f, u$ and $h=f \circ u$ be as above. Then

$$
\begin{equation*}
\rho_{f}^{u}(u(z)) \cdot l_{u}(z) \leq L_{h}(z) \quad \text { and } \quad l_{h}(z) \leq \rho_{f}^{l}(u(z)) \cdot L_{u}(z) \tag{3.1}
\end{equation*}
$$

for almost every $z \in U \backslash G_{0}$.
Proof. Fix Borel representatives of the maps $z \mapsto \operatorname{ap} \operatorname{md} u_{z}$ and $z \mapsto \operatorname{ap} \operatorname{md} h_{z}$. Towards the first inequality in (3.1), we denote

$$
G_{0}^{\prime}=G_{0} \cup\left\{z \in U: l_{u}(z)=0\right\}
$$

and notice that it suffices to prove the inequality for almost every $z \in U \backslash G_{0}^{\prime}$. By [LW17, Proposition 4.3], there are pairwise disjoint Borel sets $K_{i} \subset$ $U \backslash G_{0}^{\prime}, i \in \mathbb{N}$, so that

$$
\begin{equation*}
\left|U \backslash\left(G_{0}^{\prime} \cup\left(\cup_{i} K_{i}\right)\right)\right|_{2}=0 \tag{3.2}
\end{equation*}
$$

and so that for every $i \in \mathbb{N}$ we have
(i) ap md $u_{z}$ and ap md $h_{z}$ exist for every $z \in K_{i}$ and
(ii) for every $\varepsilon>0$ there is $r_{i}(\varepsilon)>0$ so that

$$
\begin{aligned}
& \left|d_{X}(u(z+v), u(z+w))-\operatorname{ap} \operatorname{md} u_{z}(v-w)\right| \leq \varepsilon|v-w| \quad \text { and } \\
& \left|d_{Y}(h(z+v), h(z+w))-\operatorname{apmd} h_{z}(v-w)\right| \leq \varepsilon|v-w|
\end{aligned}
$$

for every $z \in K_{i}$ and all $v, w \in \mathbb{R}^{2}$ with $|v|,|w| \leq r_{i}(\varepsilon)$ and such that $z+v, z+w \in K_{i}$.

We will show that if $i \in \mathbb{N}$ then almost every curve $\gamma$ in $X$ parametrized by arclength has the following property: almost every $t \in \gamma^{-1}\left(u\left(K_{i}\right)\right)$ satisfies

$$
\begin{equation*}
\operatorname{ap} \operatorname{md}(f \circ \gamma)_{t} \leq \frac{L_{h}(z)}{l_{u}(z)} \quad \text { for all } z \in u^{-1}(\gamma(t)) \cap K_{i} \tag{3.3}
\end{equation*}
$$

We show how to conclude the first inequality in (3.1) from (3.3). By Lemma 2.4, Corollary 2.5 and $(3.3), \rho: X \rightarrow[0, \infty]$ is a weak upper gradient of $f$, where $\rho(x)=\rho_{f}^{u}(x)$ for $x \in X \backslash u\left(K_{i}\right)$ and

$$
\rho(x)=\inf _{z \in K_{i}, u(z)=x} \frac{L_{h}(z)}{l_{u}(z)}
$$

when $x \in u\left(K_{i}\right)$. By the definition of minimal weak upper gradients, we then have that

$$
\begin{equation*}
\rho_{f}^{u}(x) \leq \rho(x) \quad \text { for almost every } x \in u\left(K_{i}\right) \tag{3.4}
\end{equation*}
$$

Since $K_{i} \subset U \backslash G_{0}^{\prime}$, we have $l_{u}>0$ and thus $J\left(\operatorname{ap} \operatorname{md} u_{z}\right)>0$ in $K_{i}$. Combining (3.4) with the Area formula (Theorem 2.6) for $u$ now yields

$$
\rho_{f}^{u}(u(z)) \cdot l_{u}(z) \leq L_{h}(z)
$$

for almost every $z \in K_{i}$. The first inequality in (3.1) follows from (3.2).
We now prove $(3.3)$. Denote by $\widehat{X} \subset X$ the set of points $x$ for which $N(x, u, U)=1$. By NR23, Remark 7.2], $\mathcal{H}^{2}(X \backslash \widehat{X})=0$. In particular, almost every rectifiable curve $\gamma:[0, \ell(\gamma)] \rightarrow X$ parametrized by arclength satisfies $\gamma(t) \in \widehat{X}$ for $\mathcal{H}^{1}$-almost every $0<t<\ell(\gamma)$.

We fix such a $\gamma$ and a density point $t_{0} \in \gamma^{-1}\left(u\left(K_{i}\right) \cap \widehat{X}\right)=$ : $T$ of $T$. By Corollary 2.5, we may moreover assume that $f \circ \gamma$ is approximately metrically differentiable at $t_{0}$. It suffices to show that $(3.3)$ holds for $t_{0}$ and the unique $z_{0}=u^{-1}\left(\gamma\left(t_{0}\right)\right) \in K_{i}$.

Fix a sequence $\left(t_{j}\right)$ of points in $T$ converging to $t$. Then $x_{j}:=\gamma\left(t_{j}\right) \rightarrow$ $\gamma\left(t_{0}\right)=: x_{0}$. Moreover, since $x_{0} \in \widehat{X}$, we have $z_{j}:=u^{-1}\left(x_{j}\right) \rightarrow z_{0}$. We are now in position to apply Property (ii) above. Denoting $y_{j}=f\left(x_{j}\right)$ for $j=0,1, \ldots$, (ii) and triangle inequality yield

$$
\begin{aligned}
& \frac{d_{X}\left(x_{j}, x_{0}\right)}{\left|z_{j}-z_{0}\right|} \geq \text { apmd } u_{z_{0}}\left(\frac{z_{j}-z_{0}}{\left|z_{j}-z_{0}\right|}\right)-o\left(\left|z_{j}-z_{0}\right|\right) \geq l_{u}\left(z_{0}\right)-o\left(\left|z_{j}-z_{0}\right|\right) \\
& \frac{d_{Y}\left(y_{j}, y_{0}\right)}{\left|z_{j}-z_{0}\right|} \leq \text { apmd } h_{z_{0}}\left(\frac{z_{j}-z_{0}}{\left|z_{j}-z_{0}\right|}\right)+o\left(\left|z_{j}-z_{0}\right|\right) \leq L_{h}\left(z_{0}\right)+o\left(\left|z_{j}-z_{0}\right|\right)
\end{aligned}
$$

Combining the inequalities, we have

$$
\begin{equation*}
\frac{d_{Y}\left(y_{j}, y_{0}\right)}{d_{X}\left(x_{j}, x_{0}\right)}=\frac{d_{Y}\left(y_{j}, y_{0}\right) \cdot\left|z_{j}-z_{0}\right|}{\left|z_{j}-z_{0}\right| \cdot d_{X}\left(x_{j}, x_{0}\right)} \leq \frac{L_{h}\left(z_{0}\right)}{l_{u}\left(z_{0}\right)}+o\left(\left|z_{j}-z_{0}\right|\right) \tag{3.5}
\end{equation*}
$$

Since $\gamma$ is parametrized by arclength, (3.5) gives (3.3). The first inequality in (3.1) follows. The second inequality follows in a similar way, namely
showing that instead of (3.3) we have

$$
\operatorname{ap} \operatorname{md}(f \circ \gamma)_{t} \geq \frac{l_{h}(z)}{L_{u}(z)}
$$

outside suitable exceptional sets. We leave the details to the reader.
Proof of Theorem 3.1. We may approximate $g$ with simple functions and replace $E$ with appropriate subsets to see that it suffices to show the claim for $g \equiv 1$. We set $E^{\prime}=E \cap \widehat{X}$, where $\widehat{X}$ is as in the proof of Proposition 3.2, and obtain

$$
\begin{equation*}
N\left(y, h, u^{-1}\left(E^{\prime}\right)\right)=\sum_{x \in f^{-1}(y)} N\left(x, u, u^{-1}\left(E^{\prime}\right)\right)=N\left(y, f, E^{\prime}\right) \tag{3.6}
\end{equation*}
$$

for every $y \in f\left(E^{\prime}\right)$.
The area formula (Theorem 2.6) implies

$$
\begin{aligned}
\int_{E} \rho_{f}^{u}(x) \rho_{f}^{l}(x) d \mathcal{H}^{2} & =\int_{E^{\prime}} \rho_{f}^{u}(x) \rho_{f}^{l}(x) N\left(x, u, u^{-1}\left(E^{\prime}\right)\right) d \mathcal{H}^{2} \\
& =\int_{u^{-1}\left(E^{\prime}\right)} \rho_{f}^{u}(u(z)) \rho_{f}^{l}(u(z)) J\left(\operatorname{ap} \operatorname{md} u_{z}\right) d z
\end{aligned}
$$

By Lemma 2.9, $J\left(\operatorname{ap} \operatorname{md} u_{z}\right) \leq 2 L_{u}(z) \cdot l_{u}(z)$ for almost every $z \in u^{-1}\left(E^{\prime}\right)$. Moreover, it follows from the proof of Theorem 2.7 given in NR22 that we can choose $u$ so that the John ellipse of ap md $u_{z}$ (see 2.6) is a disk. Then $L_{u}(z) \leq \sqrt{2} l_{u}(z)$, which leads to
$J\left(\operatorname{ap} \mathrm{md} u_{z}\right) \leq 2 L_{u}(z) \cdot l_{u}(z) \leq 2 \sqrt{2} \cdot l_{u}(z)^{2} \quad$ for almost every $z \in u^{-1}\left(E^{\prime}\right)$. Combining with Lemma 2.10 and Proposition 3.2 , we conclude that

$$
\int_{E} \rho_{f}^{u}(x) \rho_{f}^{l}(x) d \mathcal{H}^{2} \leq 2 \sqrt{2} \int_{u^{-1}\left(E^{\prime}\right)} L_{h}(z) l_{h}(z) d z
$$

Applying Lemma 2.9 and the area formula (Theorem 2.6) to $h$, we finally obtain

$$
\begin{aligned}
\int_{E} \rho_{f}^{u}(x) \rho_{f}^{l}(x) d \mathcal{H}^{2} & \leq 4 \sqrt{2} \int_{u^{-1}\left(E^{\prime}\right)} J\left(\operatorname{ap} \operatorname{md} h_{z}\right) d z \\
& =4 \sqrt{2} \int_{f\left(E^{\prime}\right)} N\left(y, h, u^{-1}\left(E^{\prime}\right)\right) d y
\end{aligned}
$$

The theorem follows by combining with (3.6).

## 4. Openness and discreteness

Throughout this section let $f$ be as in Theorem 1.2, i.e., $f \in N_{\mathrm{loc}}^{1,2}\left(X, \mathbb{R}^{2}\right)$ is non-constant, sense-preserving and satisfies $K_{f} \in L_{\mathrm{loc}}^{1}(X)$. Recall that $f$ is continuous by Remark 2.3 .

A map $f: X \rightarrow \mathbb{R}^{2}$ is light if $f^{-1}(y)$ is totally disconnected for every $y \in \mathbb{R}^{2}$. It is well-known that if $f$ is continuous, sense-preserving and light, then $f$ is open and discrete [TY62], [Ric93, Lemma VI.5.6]. Thus, in order
to prove Theorem 1.2 it suffices to show that $f$ is in fact light. The proof of this fact relies on the following two propositions involving estimates on the multiplicity of $f$ (recall notation $N(y, h, A)$ for multiplicity in (2.4).

Proposition 4.1. Suppose that there are $s, r_{0}>0$ and $C>0$ such that

$$
\begin{equation*}
\int_{0}^{2 \pi} N\left(f\left(x_{0}\right)+r e^{i \theta}, f, B\left(x_{0}, s\right)\right) d \theta \leq C \log \frac{1}{r} \tag{4.1}
\end{equation*}
$$

for all $r<r_{0}$. Then the $x_{0}$-component of $f^{-1}\left(f\left(x_{0}\right)\right)$ either is $\left\{x_{0}\right\}$ or contains an open neighborhood of $x_{0}$.

Recall that $X$ is homeomorphic to a planar domain. In particular, for every $x_{0} \in X$ there is $s>0$ so that $\bar{B}\left(x_{0}, 2 s\right)$ is a compact subset of $X$.

Proposition 4.2. Let $x_{0} \in X$ and $s>0$ so that $\bar{B}\left(x_{0}, 2 s\right) \subset X$ is compact. Then Condition (4.1) holds with some $r_{0}, C>0$.

Theorem 1.2 follows by combining Propositions 4.1 and 4.2 . since $f$ is not constant, for every $y_{0} \in f(X)$ every component $F$ of $f^{-1}\left(y_{0}\right)$ contains a point $x_{0} \in X$ which is a boundary point of $F$. Combining Propositions 4.1 and 4.2, we see that $F=\left\{x_{0}\right\}$. We conclude that $f$ is light and therefore open and discrete.
4.1. Proof of Proposition 4.1, Let $f: X \rightarrow \mathbb{R}^{2}$ be a map of finite distortion and $\Gamma$ a curve family in $X$. We define the weighted modulus

$$
\operatorname{Mod}_{K^{-1}} \Gamma=\inf _{g} \int_{X} \frac{g(x)^{2}}{K_{f}(x)} d \mathcal{H}^{2}
$$

where the infimum is taken over all weakly admissible functions $g$ for $\Gamma$.
Let $u: U \rightarrow X$ be a weakly $(4 / \pi)$-quasiconformal parametrization of $X$ as in Theorem 2.7. Let $G_{0} \subset U$ and $X_{0}=u\left(G_{0}\right) \subset X$ be as in the paragraph preceding Theorem 3.1. Recall that $\left|G_{0}\right|_{2}=0$. We set $X^{\prime}:=X \backslash X_{0}$.

Lemma 4.3. Let $\Gamma^{\prime}$ be a family of curves in $\Omega \subset X$ with $\mathcal{H}^{1}\left(|\gamma| \cap X_{0}\right)=0$ for every $\gamma \in \Gamma^{\prime}$. Then

$$
\operatorname{Mod}_{K^{-1}} \Gamma^{\prime} \leq 4 \sqrt{2} \int_{\mathbb{R}^{2}} g(y)^{2} N(y, f, \Omega) d y
$$

whenever $g$ is admissible for $\Gamma=f\left(\Gamma^{\prime}\right)$.
Proof. Fix an admissible $g$ for $\Gamma$, and let $g^{\prime}: X \rightarrow \mathbb{R}$,

$$
g^{\prime}(x):=g(f(x)) \cdot \rho_{f}^{u}(x) \cdot \chi_{\Omega \cap X^{\prime}}(x) .
$$

Here, $\chi_{E}$ denotes the indicator function on a set $E \subset X$, i.e., $\chi_{E}(x)=1$ if $x \in E$ and $\chi_{E}(x)=0$ else. For almost every $\gamma \in \Gamma^{\prime}$ we have that $f$ is absolutely continuous on $\gamma, \mathcal{H}^{1}\left(|\gamma| \cap X_{0}\right)=0$, and

$$
\int_{\gamma} g^{\prime} d s=\int_{\gamma} g(f(x)) \cdot \rho_{f}^{u}(x) d s \geq \int_{f \circ \gamma} g d s,
$$

see Corollary 2.5. Since $g$ is admissible for $\Gamma=f\left(\Gamma^{\prime}\right)$, it follows that $g^{\prime}$ is weakly admissible for $\Gamma^{\prime}$. Moreover,

$$
\begin{aligned}
\operatorname{Mod}_{K^{-1}} \Gamma^{\prime} & \leq \int_{X} \frac{g^{\prime}(x)^{2}}{K_{f}(x)} d s=\int_{\Omega \cap X^{\prime}} g(f(x))^{2} \cdot \rho_{f}^{u}(x) \rho_{f}^{l}(x) d s \\
& \leq 4 \sqrt{2} \int_{\mathbb{R}^{2}} g(y)^{2} \cdot N(y, f, \Omega) d y,
\end{aligned}
$$

where the last inequality follows from the area inequality, Theorem 3.1.
Lemma 4.4. Let $\varphi \in N_{l o c}^{1,2}(X, \mathbb{R})$, and consider $E \subset \mathbb{R}$ with $|E|_{1}>0$ and so that each level set $\varphi^{-1}(t), t \in E$, contains a non-degenerate continuum $\eta_{t}$. Then $\mathcal{H}^{1}\left(\eta_{t} \cap X_{0}\right)=0$ for almost every $t \in E$.

Proof. Note that $\widehat{\varphi}=\varphi \circ u$ is in $N_{\text {loc }}^{1,2}(U, \mathbb{R})$. For every $t \in E$, let $\widehat{\eta_{t}}=u^{-1}\left(\eta_{t}\right)$. Then, since $u$ is continuous and proper, $\widehat{\eta}_{t}$ is a non-degenerate continuum for every $t \in E$. Moreover, the coarea inequality (Theorem 2.2) shows that $\mathcal{H}^{1}\left(\widehat{\eta}_{t}\right)<\infty$ for almost every $t \in E$. For every such $t$, there is a surjective two-to-one 1-Lipschitz curve

$$
\widehat{\gamma_{t}}:\left[0,2 \mathcal{H}^{1}\left(\widehat{\left(\eta_{t}\right.}\right)\right] \rightarrow \widehat{\eta_{t}},
$$

cf. RR19, Proposition 5.1]. Let $\widehat{\Gamma}$ be the family of the curves $\widehat{\gamma_{t}}$, and let $g: U \rightarrow[0, \infty]$ be admissible for $\widehat{\Gamma}$. We apply the coarea inequality for Sobolev functions and Hölder's inequality to obtain

$$
\begin{aligned}
|E|_{1} & \leq \int_{E}^{*} \int_{\widehat{\gamma_{t}}} g d s d t \leq 2 \int_{E}^{*} \int_{\widehat{\gamma_{t}}} g d \mathcal{H}^{1} d t \leq \frac{8}{\pi} \int_{\widehat{\varphi}^{-1}(E)} g \cdot \rho_{\widehat{\varphi}}^{u} d \mathcal{H}^{2} \\
& \leq \frac{8}{\pi}\left(\int_{\widehat{\varphi}^{-1}(E)} g^{2} d \mathcal{H}^{2}\right)^{1 / 2}\left(\int_{\widehat{\varphi}^{-1}(E)}\left(\rho_{\widehat{\varphi}}^{u}\right)^{2} d \mathcal{H}^{2}\right)^{1 / 2}
\end{aligned}
$$

Since $\rho_{\widehat{\varphi}}^{u} \in L_{\text {loc }}^{2}(U)$ and $|E|_{1}>0$ it follows that $\operatorname{Mod}(\widehat{\Gamma})>0$. As a Sobolev function, $u$ is therefore absolutely continuous along $\widehat{\gamma_{t}}$ for almost every $t \in E$, see e.g. HKST15, Lemma 6.3.1]. Moreover, for almost every $t \in E$ we have that $\mathcal{H}^{1}\left(\widehat{\eta_{t}} \cap G_{0}\right)=0$, since $\left|G_{0}\right|_{2}=0$. Combining these two facts shows that $\mathcal{H}^{1}\left(\eta_{t} \cap X_{0}\right)=0$ for almost every $t \in E$.

Lemma 4.5. Let $V \subset X$ be open and connected, and $I, J \subset V$ disjoint nontrivial continua. There are $E \subset \mathbb{R},|E|_{1}>0$, and a family $\Gamma^{\prime}=\left\{\gamma_{t}: t \in E\right\}$ satisfying
(1) every $\gamma_{t} \in \Gamma^{\prime}$ is a non-degenerate curve connecting I and $J$ in $V$,
(2) there exists $\varphi \in N_{\text {loc }}^{1,2}(V, \mathbb{R})$ such that for every $t \in E$ the curve $\gamma_{t} \in \Gamma^{\prime}$ has image in the level set $\varphi^{-1}(t)$, and
(3) $\operatorname{Mod}_{K^{-1}} \Gamma^{\prime}>0$.

Proof. Replacing $V$ with a compactly connected subdomain if necessary, we may assume that

$$
\begin{equation*}
\int_{V} K_{f}(x) d \mathcal{H}^{2}(x)=K<\infty . \tag{4.2}
\end{equation*}
$$

Fix points $a \in I$ and $b \in J$ and a continuous curve $\eta$ joining $a$ and $b$ in $V$. Define $\varphi: X \rightarrow \mathbb{R}$ by $\varphi(x)=\operatorname{dist}(x,|\eta|)$. As described in the proof of Raj17, Proposition 3.5], we find $\varepsilon^{\prime}>0$, a set $E_{0} \subset\left(0, \varepsilon^{\prime}\right)$ with $\mathcal{H}^{1}\left(E_{0}\right)=0$, and for every $t \in E=\left(0, \varepsilon^{\prime}\right) \backslash E_{0}$ a rectifiable injective curve $\gamma_{t}$ joining $I$ and $J$ in $V$, with image in the level set $\varphi^{-1}(t)$. We set $\Gamma^{\prime}=\left\{\gamma_{t}: t \in E\right\}$.

Let $g: V \rightarrow[0, \infty]$ be admissible for $\Gamma^{\prime}$. We apply the coarea inequality for Lipschitz maps (Theorem 2.1) and Hölder's inequality to obtain

$$
\begin{aligned}
\varepsilon^{\prime} & \leq \int_{0}^{\varepsilon^{\prime}} \int_{\gamma_{t}} g d s d t \leq \frac{4}{\pi} \int_{V} g(x) K_{f}(x)^{-1 / 2} K_{f}(x)^{1 / 2} d \mathcal{H}^{2}(x) \\
& \leq \frac{4}{\pi}\left(\int_{V} K_{f}(x) d \mathcal{H}^{2}(x)\right)^{1 / 2}\left(\int_{V} \frac{g(x)^{2}}{K_{f}(x)} d \mathcal{H}^{2}(x)\right)^{1 / 2}
\end{aligned}
$$

Combining with 4.2) gives

$$
\operatorname{Mod}_{K^{-1}} \Gamma^{\prime} \geq\left(\frac{\pi \varepsilon^{\prime}}{4 K}\right)^{2}>0
$$

where we used that the estimate above holds for all admissible functions.
If $Z$ is a metric surface, $G \subset Z$ a domain, and $E, F \subset \bar{G}$ disjoint sets, we denote by $\Gamma(E, F ; G)$ the family of curves joining $E$ and $F$ in $\bar{G}$.
Lemma 4.6. For any $\varepsilon>0$ the function $g_{\varepsilon}: \mathbb{R}^{2} \rightarrow[0, \infty)$ defined by

$$
g_{\varepsilon}(y)=\varepsilon\left(|y| \log \frac{1}{|y|} \log \log \frac{1}{|y|}\right)^{-1} \chi_{\mathbb{D}\left(0, e^{-2}\right)}
$$

is admissible for $\Gamma\left(\{0\}, \partial \mathbb{D}\left(0, e^{-2}\right) ; \mathbb{R}^{2}\right)$ and

$$
\int_{\mathbb{R}^{2}} g_{\varepsilon}(y)^{2} \log \frac{1}{|y|} d y \rightarrow 0
$$

as $\varepsilon \rightarrow 0$.
Proof. Fix $\gamma \in \Gamma\left(\{0\}, \partial \mathbb{D}\left(0, e^{-2}\right) ; \mathbb{R}^{2}\right)$. We may assume that $\gamma:[0, \ell(\gamma)] \rightarrow$ $\mathbb{R}^{2}$ is parametrized by arclength and $\gamma(0)=0$. Then $\ell(\gamma) \geq e^{-2}$ and $|\gamma(t)| \leq$ $t$ for every $0 \leq t \leq \ell(\gamma)$. We compute

$$
\begin{aligned}
\int_{\gamma} g_{1} d s & =\int_{0}^{\ell(\gamma)} g_{1}(\gamma(t)) d t \\
& =\int_{0}^{\ell(\gamma)}\left(|\gamma(t)| \log \frac{1}{|\gamma(t)|} \log \log \frac{1}{|\gamma(t)|}\right)^{-1} d t \\
& \geq \int_{0}^{e^{-2}}\left(t \log \frac{1}{t} \log \log \frac{1}{t}\right)^{-1} d t=\infty
\end{aligned}
$$

where the last equality follows since

$$
\frac{d}{d s} \log \log \log \frac{1}{s}=-\left(s \log \frac{1}{s} \log \log \frac{1}{s}\right)^{-1}
$$

Thus, $g_{\varepsilon}=\varepsilon \cdot g_{1}$ is admissible for $\Gamma\left(\{0\}, \partial \mathbb{D}\left(0, e^{-2}\right) ; \mathbb{R}^{2}\right)$ for any $\varepsilon>0$.
In order to prove the second claim we use polar coordinates and compute

$$
\begin{aligned}
\int_{\mathbb{R}^{2}} g_{\varepsilon}(y)^{2} \log \frac{1}{|y|} d y & =\varepsilon^{2} \int_{\mathbb{R}^{2}}\left(|y|^{2} \log \frac{1}{|y|}\left(\log \log \frac{1}{|y|}\right)^{2}\right)^{-1} \chi_{\mathbb{D}\left(0, e^{-2}\right)} d y \\
& =\varepsilon^{2} \int_{0}^{2 \pi} \int_{0}^{e^{-2}}\left(r \log \frac{1}{r}\left(\log \log \frac{1}{r}\right)^{2}\right)^{-1} d r d \varphi
\end{aligned}
$$

The last term converges to 0 as $\varepsilon \rightarrow 0$ since

$$
\frac{d}{d s}\left(\log \log \frac{1}{s}\right)^{-1}=\left(s \log \frac{1}{s}\left(\log \log \frac{1}{s}\right)^{2}\right)^{-1}
$$

The second claim follows.
We are now able to prove Proposition 4.1. Let $V_{0}$ be the $x_{0}$-component of $B\left(x_{0}, s\right)$. Denote the $x_{0}$-component of $f^{-1}\left(f\left(x_{0}\right)\right) \cap V_{0}$ by $J$. We may assume that $V_{0} \backslash f^{-1}\left(f\left(x_{0}\right)\right) \neq \emptyset$, since otherwise there is nothing to prove. Towards contradiction, assume that $J$ is a non-trivial continuum. Fix another nontrivial continuum $I \subset V_{0} \backslash f^{-1}\left(f\left(x_{0}\right)\right)$.

By scaling and translating the target we may assume that $f\left(x_{0}\right)=0$, $f(I) \cap \mathbb{D}\left(0, e^{-2}\right)=\emptyset$, and that the constant $r_{0}$ in Condition 4.1) satisfies $r_{0} \geq e^{-2}$. Let $\Gamma^{\prime}$ be the curve family from Lemma 4.5. Note that $\Gamma=f\left(\Gamma^{\prime}\right)$ is a subfamily of $\Gamma\left(\{0\}, \partial \mathbb{D}\left(0, e^{-2}\right) ; \mathbb{R}^{2}\right)$. Hence, we know from Lemma 4.6 that for any $\varepsilon>0$ the function $g_{\varepsilon}$ is admissible for $\Gamma$. Lemma 4.4 implies that Lemma 4.3 can be applied to our setting and thus

$$
\operatorname{Mod}_{K^{-1}} \Gamma^{\prime} \leq 4 \sqrt{2} \int_{\mathbb{R}^{2}} g_{\varepsilon}(y)^{2} N\left(y, f, B\left(x_{0}, s\right)\right) d y
$$

Since $g_{\varepsilon}$ is symmetric with respect to the origin, combining Assumption (4.1) with polar coordinates yields

$$
\begin{array}{r}
\int_{\mathbb{R}^{2}} g_{\varepsilon}(y)^{2} N\left(y, f, B\left(x_{0}, s\right)\right) d y=\int_{0}^{e^{-2}} r g_{\varepsilon}(r)^{2} \int_{0}^{2 \pi} N\left(r e^{i \theta}, f, B\left(x_{0}, s\right)\right) d \theta d r \\
\leq C \int_{0}^{e^{-2}} r g_{\varepsilon}(r)^{2} \log \frac{1}{r} d r=C \int_{\mathbb{R}^{2}} g_{\varepsilon}(y)^{2} \log \frac{1}{|y|} d y
\end{array}
$$

By the second part of Lemma 4.6, the right hand integral converges to 0 as $\varepsilon$ goes to 0 . Thus, $\operatorname{Mod}_{K^{-1}} \Gamma^{\prime}=0$, contradicting Lemma 4.5. The proof is complete.
4.2. Proof of Proposition 4.2. Let $x_{0}$ and $s$ be as in the statement. We may assume that $f\left(x_{0}\right)=0$. We first show that $f^{-1}(y)$ is totally disconnected for most points $y \in f(X)$ around 0 .

Lemma 4.7. Let $\beta^{\prime}$ be the set of those $0 \leq \theta<2 \pi$ for which there is $R_{\theta}>0$ so that $f^{-1}\left(R_{\theta} e^{i \theta}\right)$ contains a non-degenerate continuum. Then $\left|\beta^{\prime}\right|_{1}=0$.

Proof. We define

$$
\varphi: X \backslash f^{-1}(0) \rightarrow \mathbb{S}^{1}, \quad \varphi(x)=\frac{f\left(x_{0}\right)}{\left|f\left(x_{0}\right)\right|}
$$

and note that $\rho_{f}^{u} /|f|$ is a weak upper gradient of $\varphi$. Towards a contradiction we assume that $\left|\beta^{\prime}\right|_{1}>0$. Then there are $\delta, \varepsilon>0$ and a set $\beta_{\delta}^{\prime} \subset \beta^{\prime}$, $\left|\beta_{\delta}^{\prime}\right|_{1}>0$, such that for every $\theta \in \beta_{\delta}^{\prime}$ there exists $R_{\theta} \in[\varepsilon, 1]$ for which $f^{-1}\left(R_{\theta} e^{i \theta}\right)$ contains a continuum $E_{\theta}$ with $\mathcal{H}^{1}\left(E_{\theta}\right) \geq \delta$. As in the proof of Lemma 4.4, we see that almost every $\theta \in \beta_{\delta}^{\prime}$ the continuum $E_{\theta}$ is the image of a rectifiable curve $\gamma_{\theta}$, and the modulus of the family of such curves is positive. By the definition of lower gradients and since $f \circ \gamma_{\theta}$ is constant by construction, we then have that $\rho_{f}^{l}=0$ almost everywhere in

$$
E=\bigcup_{\theta \in \beta_{\delta}^{\prime}} E_{\theta}
$$

Furthermore, since $f$ has finite distortion, also $\rho_{f}^{u}=0$ almost everywhere in $E$. Let

$$
F=\left\{x \in X:|f(x)| \geq \varepsilon, \rho_{f}^{u}(x)=0\right\} \supset E
$$

We apply the Sobolev coarea inequality (Theorem 2.2) to compute

$$
0<\delta\left|\beta_{\delta}^{\prime}\right|_{1} \leq \int_{\beta_{\delta}^{\prime}}^{*} \mathcal{H}^{1}\left(E_{\theta}\right) d \theta \leq \frac{4}{\pi} \int_{F} \frac{\rho_{f}^{u}}{|f|} d \mathcal{H}^{2}=0
$$

a contradiction. The proof is complete.
Lemma 4.8. Let $\beta^{\prime}$ be the set in Lemma 4.7. There exists $\beta \supset \beta^{\prime}$ with $|\beta|_{1}=0$, and an open $\Omega^{\prime} \subset X$, such that
(1) $\left.f\right|_{\Omega^{\prime}}$ is a local homeomorphism, and
(2) if $V=\left\{t e^{i \theta}: t>0, \theta \in \beta\right\}$, then $\Omega^{\prime} \supset X \backslash f^{-1}(V)$.

Proof. Set $V^{\prime}=\left\{t e^{i \theta}: \theta \in \beta^{\prime}, t>0\right\}$. Let $y \in f(X) \backslash V^{\prime}$ and $x \in{\underset{\sim}{f}}^{-1}(y)$. Then, since $\{x\}$ is a component of $f^{-1}(y)$, there is a Jordan domain $\widetilde{U}_{x}$ in $X$ such that $x \in \widetilde{U}_{x}$ and $y \notin f\left(\partial \widetilde{U}_{x}\right)$. Let $W_{x}$ be the $y$-component of $\mathbb{R}^{2} \backslash f\left(\partial \widetilde{U}_{x}\right)$ and $U_{x}$ the $x$-component of $f^{-1}\left(W_{x}\right)$. It follows that $f\left(\partial U_{x}\right) \subset \partial W_{x}$. Indeed, otherwise there is a point $a \in \partial U_{x}$ with $f(a) \in W_{x}$ and therefore there exists a neighbourhood $Y$ of $f(a)$ in $W_{x}$, but the $a$-component of $f^{-1}(Y)$ is not contained in $U_{x}$, which is a contradiction.

The assumption that $f$ is sense-preserving now implies $f\left(\partial U_{x}\right)=\partial W_{x}$. Using basic degree theory, we conclude that $f^{-1}(z)$ has at $\operatorname{most} \operatorname{deg}\left(y, f, U_{x}\right)$
components in $U_{x}$ for every $z \in W_{x}$. Furthermore, arguing as in the proof of Lemma 4.7 we see that for almost every such $z$ all of these components are points. In other words,

$$
N\left(z, f, U_{x}\right) \leq \operatorname{deg}\left(y, f, U_{x}\right)<\infty
$$

for almost every $z \in W_{x}$. In particular, every $x \in U_{x}$ satisfies the conditions in Proposition 4.1, and therefore $\left.f\right|_{U_{x}}$ is open and discrete.

We have established the following.
(i) If $y \in f(X) \backslash V^{\prime}$ and $x \in f^{-1}(y)$, then $x$ has a neighbourhood $U_{x}$ such that $\left.f\right|_{U_{x}}$ is open and discrete.
We define

$$
\widehat{\Omega}=\left\{x \in X: x \text {-component of } f^{-1}(f(x)) \text { is }\{x\}\right\}
$$

Note that if $x \in \widehat{\Omega}$, then there exists a neighbourhood $Y$ of $f(x)$ such that the closure of the $x$-component of $f^{-1}(Y)$ is compact. As above, we find a neighbourhood $U_{x}$ of $x$ such that $\left.f\right|_{U_{x}}$ is open and discrete. In particular, $\widehat{\Omega}$ is open. Moreover, it follows from (i) that $\widehat{\Omega} \supset X \backslash f^{-1}\left(V^{\prime}\right)$. We have shown that
(ii) $\widehat{\Omega}$ is open, $\left.f\right|_{\widehat{\Omega}}$ is open and discrete, and $\widehat{\Omega} \supset X \backslash f^{-1}\left(V^{\prime}\right)$.

Denote by $\mathcal{B}_{f}$ the branch set of $\left.f\right|_{\widehat{\Omega}}$, i.e., the set of points where $\left.f\right|_{\widehat{\Omega}}$ fails to be locally invertible, and define

$$
\beta^{\prime \prime}=\left\{0 \leq \theta<2 \pi: R e^{i \theta} \in f\left(B_{f}\right) \text { for some } R>0\right\}
$$

Recall that $\mathcal{B}_{f}$ is closed and countable, thus $\beta^{\prime \prime}$ is countable. It follows from Lemma 4.7 and (ii) that the sets $\Omega^{\prime}=\widehat{\Omega} \backslash \mathcal{B}_{f}$ and $\beta=\beta^{\prime} \cup \beta^{\prime \prime}$ possess the desired properties.
Lemma 4.9. Let $m \in \mathbb{N}, 0<r<e^{-2}$, and assume that $\bar{B}\left(x_{0}, 2 s\right)$ is compact and satisfies $f\left(\bar{B}\left(x_{0}, 2 s\right)\right) \subset \mathbb{D}(0,1)$. If

$$
E_{m}=\left\{0 \leq \theta<2 \pi: N\left(r e^{i \theta}, f, B\left(x_{0}, s\right)\right)=m\right\},
$$

then

$$
m\left|E_{m}\right|_{1} \leq \frac{64 \sqrt{2}}{\pi s^{2}} \int_{F_{m}} K_{f} d \mathcal{H}^{2} \cdot \log \frac{1}{r},
$$

where $F_{m}=\left\{x \in X: \arg (f(x)) \in E_{m}\right\}$.
Proof. We assume $\left|E_{m}\right|_{1}>0$, otherwise there is nothing to show. Let $\beta$ and $\Omega^{\prime}$ be as in Lemma 4.8. We set $E_{m}^{\prime}=E_{m} \backslash \beta$ and note that $\left|E_{m}^{\prime}\right|_{1}=\left|E_{m}\right|_{1}$ since $|\beta|_{1}=0$. We also denote

$$
F_{m}^{\prime}=\left\{x \in X: \arg (f(x)) \in E_{m}^{\prime}\right\} \subset F_{m}
$$

Fix $\theta \in E_{m}^{\prime}$, then

$$
f^{-1}\left(\left\{t e^{i \theta}: t \geq r\right\}\right) \subset \Omega^{\prime} .
$$

We can therefore apply path lifting of local homeomorphisms to curves $I_{\theta}=$ $\left\{t e^{i \theta}: r \leq t \leq 1\right\}$ as follows: if $\left\{x_{1}, \ldots, x_{m}\right\}=f^{-1}\left(r e^{i \theta}\right) \cap B(x, s)$ then for every $j \in\{1, \ldots, m\}$ there exists a maximal lift $\gamma_{\theta}^{j}$ of $I_{\theta}$ starting at $x_{j}$,
see Ric93, Theorem II.3.2]. Note that if $\varphi: X \rightarrow[0,2 \pi)$ is defined by $\varphi(x)=\arg (f(x))$, then the image of each $\gamma_{\theta}^{j}$ is contained in the level set $\varphi^{-1}(\theta)$.

Since $\bar{B}(x, 2 s)$ is compact and $f(\bar{B}(x, 2 s)) \subset \mathbb{D}(0,1)$, every curve $\gamma_{\theta}^{j}$ connects $B(x, s)$ and $X \backslash B(x, 2 s)$, and so $\mathcal{H}^{1}\left(\left|\gamma_{\theta}^{j}\right|\right) \geq s$. Moreover, $\left.f\right|_{\left|\gamma_{\theta}^{j}\right|}$ is injective. It follows that

$$
\begin{equation*}
s \cdot m \leq \sum_{j=1}^{m} \mathcal{H}^{1}\left(\left|\gamma_{\theta}^{j}\right|\right) \leq \mathcal{H}^{1}(\{x \in X: \arg (f(x))=\theta\}) \tag{4.3}
\end{equation*}
$$

for every $\theta \in E_{m}^{\prime}$.
We combine (4.3) with the Sobolev coarea inequality (Theorem 2.2) and Hölder's inequality to compute

$$
\begin{aligned}
s \cdot m \cdot\left|E_{m}\right|_{1} & =s \cdot m \cdot\left|E_{m}^{\prime}\right|_{1} \\
& \leq \int_{E_{m}^{\prime}} \mathcal{H}^{1}(\{x \in X: \arg (f(x))=\theta\}) d \theta \\
& \leq \frac{4}{\pi} \int_{F_{m}} \frac{\rho_{f}^{u}}{|f|} d \mathcal{H}^{2} \leq \frac{4}{\pi} \int_{F_{m}} K_{f}^{1 / 2} \cdot \frac{\left(\rho_{f}^{u} \cdot \rho_{f}^{l}\right)^{1 / 2}}{|f|} d \mathcal{H}^{2} \\
& \leq \frac{4}{\pi}\left(\int_{F_{m}} K_{f} d \mathcal{H}^{2}\right)^{1 / 2}(\underbrace{\int_{F_{m}^{\prime}} \frac{\rho_{f}^{u} \cdot \rho_{f}^{l}}{|f|^{2}} d \mathcal{H}^{2}}_{=: I})^{1 / 2} .
\end{aligned}
$$

For each $j \in\{1, \ldots, m\}$ we define the curve family

$$
\Gamma_{j}^{\prime}=\left\{\gamma_{\theta}^{j}: t \in E_{m}^{\prime}\right\}
$$

Lemma 4.4 applied to $\Gamma_{j}^{\prime}$ shows that $\mathcal{H}^{1}\left(\left|\gamma_{\theta}^{j}\right| \cap X_{0}\right)=0$ for almost every $\theta \in E_{m}^{\prime}$ and every $j \in\{1, \ldots, m\}$, where $X_{0}$ is as in Theorem 3.1. Hence, if

$$
F_{m}^{\prime \prime}=\left\{x \in X: x \in\left|\gamma_{\theta}^{j}\right| \text { for some } \theta \in E_{m}^{\prime} \text { and } 1 \leq j \leq m\right\} \supset F_{m}^{\prime},
$$

then $\mathcal{H}^{2}\left(F_{m}^{\prime \prime} \cap X_{0}\right)=0$ and $N\left(y, f, F_{m}^{\prime \prime}\right) \leq m$ for every $y \in \mathbb{R}^{2}$. By the area inequality (Theorem 3.1) and polar coordinates,

$$
I \leq 4 \sqrt{2} \int_{E_{m}} \int_{r}^{1} \frac{N\left(s e^{i \theta}, f, F_{m}^{\prime \prime}\right)}{s} d s d \theta \leq 4 \sqrt{2} \cdot\left|E_{m}\right|_{1} \cdot m \cdot \log \frac{1}{r}
$$

The lemma follows by combining the estimates.
Proposition 4.2 follows from Lemma 4.9 notice that by scaling we may assume that $f\left(\bar{B}\left(x_{0}, 2 s\right)\right) \subset \mathbb{D}(0,1)$, so that the conditions of Lemma 4.9 are satisfied. Recall that the sets $F_{m}$ are pairwise disjoint. Therefore, summing
the estimate in Lemma 4.9 over $m$ gives

$$
\begin{aligned}
\int_{0}^{2 \pi} N\left(r e^{i \theta}, f, B\left(x_{0}, s\right)\right) d \theta & =\sum_{m=1}^{\infty} m\left|E_{m}\right|_{1} \\
& \leq C \log \frac{1}{r} \sum_{m=1}^{\infty} \int_{F_{m}} K_{f}(x) d \mathcal{H}^{2} \\
& \leq C \log \frac{1}{r} \int_{X} K_{f}(x) d \mathcal{H}^{2} .
\end{aligned}
$$

We may replace $X$ with a compactly contained subdomain if necessary to guarantee that $K_{f}$ is integrable. Proposition 4.2 follows.

## 5. Regularity of the inverse

In this section we study the regularity of the inverse of mappings of finite distortion and prove Theorem 1.3. Let $f \in N_{\mathrm{loc}}^{1,2}\left(X, \Omega^{\prime}\right)$ be a homeomorphism with $K_{f} \in L_{\mathrm{loc}}^{1}(X)$, where $\Omega^{\subset} \subset \mathbb{R}^{2}$. We set $\phi=f^{-1}: \Omega^{\prime} \rightarrow X$ and define $\psi: \Omega^{\prime} \rightarrow[0, \infty]$ by

$$
\psi(y)=\frac{1}{\rho_{f}^{l}(\phi(y))}
$$

Lemma 5.1. We have

$$
\int_{E} \psi(y)^{2} d y \leq 2 \int_{\phi(E)} K_{f}(x) d \mathcal{H}^{2}(x)
$$

for every Borel set $E \subset \Omega^{\prime}$. In particular, $\psi \in L_{l o c}^{2}\left(\Omega^{\prime}\right)$.
Proof. Again, let $u: U \rightarrow X, U \subset \mathbb{R}^{2}$, be a weakly (4/ $\pi$ )-quasiconformal parametrization and $h=f \circ u$. Then $h$ is locally in $N^{1,2}\left(U, \mathbb{R}^{2}\right)$ and monotone. Therefore, $h$ satisfies Condition ( $N$ ) and consequently the euclidean area formula, see MM95. Combining the area formula with distortion estimates established in previous sections, we have

$$
\begin{aligned}
\int_{E} \psi(y)^{2} d y & =\int_{h^{-1}(E)} \frac{J\left(\operatorname{ap} \mathrm{md} h_{z}\right)}{\rho_{f}^{l}(u(z))^{2}} d z=\int_{h^{-1}(E)} \frac{L_{h}(z) \cdot l_{h}(z)}{\rho_{f}^{l}(u(z))^{2}} d z \\
& \leq \int_{h^{-1}(E)} \frac{\rho_{f}^{u}(u(z)) \cdot \rho_{f}^{l}(u(z))}{\rho_{f}^{l}(u(z))^{2}} L_{u}(z)^{2} d z \\
& \leq 2 \int_{h^{-1}(E)} K_{f}(u(z)) \cdot J\left(\operatorname{ap} \operatorname{md} u_{z}\right) d z .
\end{aligned}
$$

Here the second equality holds since both the domain and target of $h$ are euclidean domains and the first inequality holds by Lemma 2.10 and Proposition 3.2 . The second inequality holds by (2.6) and recalling that we can choose $u$ so that the John ellipses of ap md $u_{z}$ are disks for almost every $z$. The claim now follows from the area formula for $u$ (Theorem 2.6).

Lemma 5.2. Suppose $\alpha: X \rightarrow \mathbb{R}$ is 1 -Lipschitz. Then $v=\alpha \circ \phi$ is absolutely continuous on almost every line parallel to coordinate axes, and $\left|\partial_{j} v\right| \leq$ $\frac{16 \sqrt{2}}{\pi} \cdot \psi$ almost everywhere for $j=1,2$.

Proof. It suffices to consider horizontal lines. Fix a square $Q \subset \Omega^{\prime}$ with sides parallel to coordinate axes. By scaling and translating, we may assume that $Q=[0,1]^{2}$.

By Lebesgue's theorem, there exists a set $\Phi \subset(0,1)$ of full measure so that if $s_{0} \in \Phi$ then

$$
\begin{equation*}
\frac{1}{2 \varepsilon} \int_{F_{\varepsilon}} \psi(y) d y=\frac{1}{2 \varepsilon} \int_{s_{0}-\varepsilon}^{s_{0}+\varepsilon} \int_{t_{1}}^{t_{2}} \psi(t, s) d t d s \rightarrow \int_{t_{1}}^{t_{2}} \psi\left(t, s_{0}\right) d t \tag{5.1}
\end{equation*}
$$

as $\varepsilon \rightarrow 0$ for every $0 \leq t_{1}<t_{2} \leq 1$, where $F_{\varepsilon}=\left[t_{1}, t_{2}\right] \times\left[s_{0}-\varepsilon, s_{0}+\varepsilon\right]$.
Fix $s_{0} \in \Phi$. The claim now follows from Lemma 5.1 if we can show that

$$
\begin{equation*}
\left|\phi\left(t_{2}, s_{0}\right)-\phi\left(t_{1}, s_{0}\right)\right| \leq \frac{16 \sqrt{2}}{\pi} \int_{t_{1}}^{t_{2}} \psi\left(t, s_{0}\right) d t \tag{5.2}
\end{equation*}
$$

for every $0 \leq t_{1}<t_{2} \leq 1$.
Given $0<\varepsilon<\min \left\{s_{0}, 1-s_{0}\right\}$ we set $E_{\varepsilon}=\phi\left(F_{\varepsilon}\right)$. Let $\varphi=\left.\pi_{2} \circ f\right|_{E_{\varepsilon}}$, where $\pi_{2}$ denotes projection to the $s$-axis on the $(t, s)$-plane. By continuity of $\varphi$, Lemma 4.4, and the Sobolev coarea inequality (Theorem 2.2) applied to $\varphi$, we have

$$
\begin{aligned}
\left|\phi\left(t_{2}, s_{0}\right)-\phi\left(t_{1}, s_{0}\right)\right| & \leq \delta(\varepsilon)+\frac{1}{2 \varepsilon} \int_{s_{0}-\varepsilon}^{s_{0}+\varepsilon} \mathcal{H}^{1}\left(\varphi^{-1}(s) \backslash X_{0}\right) d s \\
& \leq \delta(\varepsilon)+\frac{2}{\pi \varepsilon} \int_{E_{\varepsilon} \backslash X_{0}} \frac{\rho_{f}^{u} \cdot \rho_{f}^{l}}{\rho_{f}^{l}} \chi_{\rho_{f}^{l} \neq 0} d \mathcal{H}^{2},
\end{aligned}
$$

where $X_{0}$ is the set in the Area inequality (Theorem 3.1) and $\delta(\varepsilon) \rightarrow 0$ as $\varepsilon \rightarrow 0$. Combining with Theorem 3.1, we obtain

$$
\begin{equation*}
\left|\phi\left(t_{2}, s_{0}\right)-\phi\left(t_{1}, s_{0}\right)\right| \leq \delta(\varepsilon)+\frac{8 \sqrt{2}}{\pi \varepsilon} \int_{F_{\varepsilon}} \psi(y) d y . \tag{5.3}
\end{equation*}
$$

Now (5.2) follows by combining (5.3) and (5.1).
We are ready to prove Theorem 1.3 . By Lemma 5.1 and the ACLcharacterization of Sobolev functions (see HKST15, Theorem 6.1.17]), we see that every $v$ in Lemma 5.2 belongs to $W_{\text {loc }}^{1,2}\left(\Omega^{\prime}\right)$ and satisfies $|\nabla v| \leq \frac{32 \psi}{\pi}$ almost everywhere. Furthermore, the characterization of Sobolev maps in terms of post-compositions with 1-Lipschitz functions, i.e., in terms of the functions $v$ above (see [HKST15. Theorem 7.1.20]), shows that $\phi \in$ $N_{\text {loc }}^{1,2}\left(\Omega^{\prime}, X\right)$. The proof is complete.

## 6. Reciprocal surfaces

Recall the geometric definition of quasiconformality: homeomorphism $f: X \rightarrow Y$ is quasiconformal if there exists $C \geq 1$ such that

$$
\begin{equation*}
C^{-1} \operatorname{Mod} f(\Gamma) \leq \operatorname{Mod} \Gamma \leq C \operatorname{Mod} f(\Gamma) \tag{6.1}
\end{equation*}
$$

for each curve family $\Gamma$ in $X$.
We say that metric surface $X$ is reciprocal if there exists $\kappa>0$ such that for every topological quadrilateral $Q \subset X$ and for the families $\Gamma(Q)$ and $\Gamma^{*}(Q)$ of curves joining opposite sides of $Q$ we have

$$
\operatorname{Mod} \Gamma(Q) \cdot \operatorname{Mod} \Gamma^{*}(Q) \leq \kappa
$$

If $X$ is reciprocal, $x \in X$ and $R>0$ so that $X \backslash B(x, R) \neq \emptyset$, then by [NR22, Theorem 1.8] we have

$$
\begin{equation*}
\lim _{r \rightarrow 0} \operatorname{Mod} \Gamma(B(x, r), X \backslash B(x, R) ; X)=0 . \tag{6.2}
\end{equation*}
$$

Recall that $\Gamma(E, F ; G)$ is the family of curves joining $E$ and $F$ in $\bar{G}$.
Reciprocal surfaces are the metric surfaces that admit quasiconformal parametrizations by euclidean domains, see Raj17], [ko22], [NR22]. See Raj17, RR19], EBPC22, MW21, NR23 and NR22 for further properties of reciprocal surfaces.

It is desirable to find non-trivial conditions which imply reciprocality. For instance, one could hope that the existence of maps satisfying the conditions of Theorem 1.2 forces $X$ to be reciprocal. However, this is not the case.

Proposition 6.1. Given an increasing $\phi:[1, \infty) \rightarrow[1, \infty)$ so that $\phi(t) \rightarrow \infty$ as $t \rightarrow \infty$, there is a non-reciprocal metric surface $X$ and a homeomorphism $f: X \rightarrow \mathbb{R}^{2}$ so that $f \in N_{\text {loc }}^{1,2}\left(X, \mathbb{R}^{2}\right)$ and $\phi\left(K_{f}\right)$ is locally integrable.

The map $f_{0}$ defined in the proof below is known as Ball's map (Bal81]) and illustrates that the integrability condition in Theorem 1.2 is sharp.

Proof. Let $f_{0}: \mathbb{R}^{2} \rightarrow \mathbb{R}^{2}$ be defined by $f_{0}(x, y)=(x, \eta(x, y))$, where

$$
\eta(x, y)= \begin{cases}|x| y, & 0 \leq|x| \leq 1,0 \leq|y| \leq 1 \\ (2(|y|-1)+|x|(2-|y|)) \frac{y}{|y|}, & 0 \leq|x| \leq 1,1 \leq|y| \leq 2, \\ y, & \text { otherwise }\end{cases}
$$

Note that $f_{0}$ is not open and discrete since it maps the segment $I=$ $\{0\} \times[-1,1]$ to the origin. Also, $f_{0}$ is the identity outside $(-1,1) \times(-2,2)$. Calculating the Jacobian matrix shows that $f_{0}$ is sense-preserving and Lipschitz, $K_{f_{0}}$ is bounded outside $(-1,1) \times(-1,1)$, and

$$
\begin{equation*}
K_{f_{0}}(x, y)=\frac{1}{|x|} \quad \text { for all }(x, y) \in(-1,1) \times(-1,1) \tag{6.3}
\end{equation*}
$$

It follows that $K_{f_{0}}$ is not in $L_{\mathrm{loc}}^{1}\left(\mathbb{R}^{2}\right)$ but $K_{f_{0}} \in L_{\mathrm{loc}}^{p}\left(\mathbb{R}^{2}\right)$ for every $0<p<1$.

We change the metric on $\mathbb{R}^{2}$ to obtain the desired metric surface $X$ and $f: X \rightarrow \mathbb{R}^{2}$. Define $\omega: \mathbb{R}^{2} \rightarrow[0,1]$ by $\omega(z)=1$ when $\operatorname{dist}(z, I) \geq 1$ and by

$$
\begin{equation*}
\omega(z)=\frac{1}{\phi\left(\operatorname{dist}(z, I)^{-1}\right)} \tag{6.4}
\end{equation*}
$$

otherwise, where $I=\{0\} \times[-1,1]$. Moreover, let

$$
d_{\omega}(x, y):=\inf _{\gamma} \int_{\gamma} \omega d s
$$

where the infimum is taken over all rectifiable curves $\gamma$ connecting $x, y \in \mathbb{R}^{2}$.
Now $X=\left(\mathbb{R}^{2} / I, d_{\omega}\right)$ is homeomorphic to $\mathbb{R}^{2}$ and has locally finite $\mathcal{H}^{2}$ measure. Let $\pi: \mathbb{R}^{2} \rightarrow \mathbb{R}^{2} / I$ be the projection map, $\mathrm{id}_{\omega}: \mathbb{R}^{2} / I \rightarrow X$ the identity, and $\pi_{\omega}: \mathbb{R}^{2} \rightarrow X, \pi_{\omega}=\operatorname{id}_{\omega} \circ \pi$.

Since modulus is conformally invariant and $\omega$ is a conformal change of metric outside $I$, the family of curves joining any non-trivial continuum and the point $p:=\pi_{\omega}(I)$ in $X$ has positive modulus. By (6.2), it follows that $X$ is non-reciprocal.

We define $f: X \rightarrow \mathbb{R}^{2}$ by $f:=f_{0} \circ \pi_{\omega}^{-1}$. Then $f$ is absolutely continuous on almost every rectifiable curve in $X$, and $\rho_{f}^{u}(z) \leq(\omega(z))^{-1} \cdot L$ for almost every $z \in X$, where $L$ is the Lipschitz constant of $f_{0}$. Therefore,

$$
\int_{E}\left(\rho_{f}^{u}\right)^{2} d \mathcal{H}^{2} \leq L^{2}\left|\pi_{\omega}^{-1}(E)\right|_{2}
$$

for every Borel set $E \subset X$. We conclude that $f \in N_{\mathrm{loc}}^{1,2}\left(X, \mathbb{R}^{2}\right)$.
It remains to estimate the integral of $\phi\left(K_{f}\right)$. To this end, notice that since $\omega$ is a conformal change of metric, we have

$$
K_{f}(z)=K_{f_{0}}\left(\pi_{\omega}^{-1}(z)\right)
$$

for almost every $z \in X$. Therefore, it suffices to check that $\phi\left(K_{f}\right)$ is integrable over $E=\pi_{\omega}((-1,1) \times(-1,1))$. By (6.3) and (6.4), we have
$\int_{E} \phi\left(K_{f}(z)\right) d \mathcal{H}^{2}=\int_{(-1,1)^{2}} \phi\left(K_{f_{0}}\right) \cdot \omega^{2} d x d y \leq \int_{(-1,1)^{2}} \frac{1}{\phi\left(|x|^{-1}\right)} d x d y<\infty$.
The proof is complete.
We do not know if Proposition 6.1 remains true if the distortion is required to be bounded. We call a mapping $f: X \rightarrow \mathbb{R}^{2}$ of finite distortion quasiregular, if there is $K \geq 1$ so that $K_{f}(x) \leq K$ for almost every $x \in X$.
Question 6.2. Suppose there is a non-constant quasiregular map $f: X \rightarrow$ $\mathbb{R}^{2}$. Is $X$ reciprocal?

The more general issue behind Question 6.2 is the equivalence between different definitions of distortion. It follows from Raj17 and Wil12 that the geometric definition (6.1) of quasiconformality of a homeomorphism $f$ : $X \rightarrow \mathbb{R}^{2}$ is equivalent to the requirement that $f \in N_{\mathrm{loc}}^{1,2}\left(X, \mathbb{R}^{2}\right)$ and

$$
\begin{equation*}
\rho_{f}^{u}(x)^{2} \leq K^{\prime} J_{f}(x) \quad \text { a.e. } x \in X \tag{6.5}
\end{equation*}
$$

where $J_{f}$ is the measure derivative of the pull-back under $f$ of $|\cdot|_{2}$ with respect to $\mathcal{H}^{2}$. We do not know if these definitions are equivalent to our definition based on lower gradients.

Question 6.3. Suppose $f: X \rightarrow \mathbb{R}^{2}$ is a quasiregular homeomorphism. Is $f$ quasiconformal in the sense of (6.1) / 6.5)?

For non-homeomorphic maps the existence of $J_{f}$ and the consequences of (6.5) seem to be problematic when $X$ is a general metric surface. We have introduced the lower gradient approach above to avoid these issues.

## 7. Existence of maximal Weak lower gradients

Let $X$ and $Y$ be metric surfaces. We now complete the discussion in Section 2.3 by proving that each $f \in N_{\mathrm{loc}}^{1,2}(X, Y)$ has a maximal weak lower gradient. Precisely, we claim that there is a weak lower gradient $\rho_{f}^{l}$ of $f$ so that if $\rho^{l}$ is another weak lower gradient of $f$ then

$$
\rho_{f}^{l}(x) \geq \rho^{l}(x) \quad \text { for almost every } x \in X
$$

Moreover, $\rho_{f}^{l}$ is unique up to a set of measure zero. The proof of these facts is analogous to the existence of minimal weak upper gradients, see HKST15, Theorem 6.3.20].

First, recall that $f$ is absolutely continuous along almost every curve HKST15, Lemma 6.3.1]. It follows from HKST15, Lemma 5.2.16] that if $\rho$ is a weak lower gradient of $f$ and $\sigma: X \rightarrow[0, \infty]$ is a Borel function such that $\sigma=\rho$ almost everywhere in $X$, then $\sigma$ is a weak lower gradient of $f$. In particular, if $E \subset X$ is Borel and satisfies $\mathcal{H}^{2}(E)=0$ then $\rho \chi_{X \backslash E}$ is a weak lower gradient of $u$, compare to HKST15, Lemma 6.2.8]. We conclude that if there exists a maximal weak lower gradient $\rho_{f}^{l}$ of $f$, it has to be unique up to sets of measure zero.

To prove existence of $\rho_{f}^{l}$, we may assume without loss of generality that $\mathcal{H}^{2}(X)<\infty$. Arguing exactly as in the proof of HKST15, Lemma 6.3.8], we can show that if $\sigma, \tau \in L^{2}(X)$ are weak lower gradients of a map $f: X \rightarrow Y$ that is absolutely continuous along almost every curve in $X$ and if $E$ is a measurable subset of $X$ then the function

$$
\rho=\sigma \cdot \chi_{E}+\tau \cdot \chi_{X \backslash E}
$$

is a weak lower gradient of $f$. Now, by choosing $E=\{x \in X: \sigma>\tau\}$, it follows that $\rho: X \rightarrow[0, \infty]$ defined by

$$
\rho(x)=\max \{\sigma(x), \tau(x)\}
$$

is a 2-integrable weak lower gradient of $f$. After applying Fuglede's lemma, see e.g. [HKST15, Section 5.1], we established the following lemma.

Lemma 7.1. If $f: X \rightarrow Y$ is absolutely continuous along almost every curve, then the collection $\mathcal{L}$ of 2 -integrable weak lower gradients of $f$ is closed under pointwise maximum operations.

Let $\left(\rho_{i}\right) \subset \mathcal{L}$ be a sequence such that

$$
\lim _{i \rightarrow \infty}\left\|\rho_{i}\right\|_{L^{2}}=\sup \left\{\|\rho\|_{L^{2}}: \rho \in \mathcal{L}\right\} .
$$

By Lemma 7.1, the sequence $\left(\rho_{i}^{\prime}\right)$ given by $\rho_{i}^{\prime}(x)=\max _{1 \leq j \leq i} \rho_{j}(x)$ is in $\mathcal{L}$. Note that ( $\overline{\rho_{i}^{\prime}}$ ) is pointwise increasing. The limit function

$$
\rho_{f}^{l}:=\lim _{i \rightarrow \infty} \rho_{i}^{\prime}
$$

is Borel by HKST15, Proposition 3.3.22]. The monotone convergence theorem implies that $\rho_{i}^{\prime} \rightarrow \rho_{f}^{l}$ in $L^{2}(X)$ and by Fuglede's lemma $\rho_{f}^{l} \in \mathcal{L}$, see e.g. HKST15, Section 5.1]. By construction, $\rho_{f}^{l}$ is a maximal weak lower gradient of $f$. The proof is complete.
